Some of the topics included are: Newton's basic equations of motion; the motion of a free falling object, that neglects the effects of aerodynamics; the terminal velocity of a falling object subject to both weight and air resistance; the three forces (lift, drag, and weight) that act on a glider; and finally, the four forces that act on a powered airplane. Because aerodynamics involves both the motion of the object and the reaction of the air, there are several pages devoted to basic gas ...

The web site was prepared to provide background information on basic aerodynamics and propulsion for math and science teachers, students, and life-long learners. We have intentionally organized the Beginner's Guides to mirror the unstructured nature of the world wide web.

## **Beginner's Guide to Aeronautics**

Aero-dynamics is the study of the dynamics associated with the motions of air over a moving object. When an aircraft accelerates down the runway to take off, it produces a relative motion between the air and the aircrafts wings.

Exactly how lift is created on the wing of an airplane is still a topic that is not agreed upon by all who study aerodynamics. Traditional theory was that because of the curved surface on the top of the wing, this created a longer path than the flat surface of the bottom of the wing creating a lower pressure on the top surface causing the wing to be sucked upward.

As much as it seems sometimes that airplanes fly by magic, it's important for every pilot to understand at least the basic fundamentals of aerodynamics. These principles dictate not only how the aircraft stays aloft, but what make it either stable or unstable. Understanding these concepts will create a smoother and safer pilot.

Pressure Atmospheric pressure varies with altitude. The higher an object rises above sea level, the lower the pressure. Density It varies directly with the pressure and inversely with the temperature. With the same horse power, an aircraft can fly faster at high altitude because of less resistance of air at there.

The four forces acting on an airplane in flight are: Lift, weight (Gravity), thrust and drag Which statement relates to Bernoulli's principle? Air traveling faster over the curved upper surface of an airfoil causes lower pressure on the top surface

## **Basic Aerodynamics Flashcards | Quizlet**

Air traveling faster over the curved upper surface of an airfoil causes lower pressure on the top surface. The angle between the chord line of an airfoil and

the relative wind is known as the angle of attack. Changes in the center of pressure of a wing affect the aircraft's aerodynamic balance and controllability.

The air that travels above the wing travels a longer distance, which means it has to travel at a higher velocity than the air below resulting in a lower pressure environment. On the other hand, the air that passes below the wing doesn't have to travel as far as the air on top of the wing, so the air can travel at a lower velocity than the air above resulting in a higher pressure environment.

Aerodynamics Aerodynamics is the study of forces and the resulting motion of objects through the air. Studying the motion of air around an object allows us to measure the forces of lift, which allows an aircraft to overcome gravity, and drag, which is the resistance an aircraft “feels” as it moves through the air.

## **BASIC AERODYNAMICS - KSU**

Aerodynamics is the way air moves around things. The rules of aerodynamics explain how an airplane is able to fly. Anything that moves through air reacts to aerodynamics. A rocket blasting off the launch pad and a kite in the sky react to aerodynamics. Aerodynamics even acts on cars, since air flows around cars.

## **What Is Aerodynamics? | NASA**

Newton's three laws on force and motion are applicable to aerodynamics. The four forces acting on an aircraft are weight, lift, thrust, and drag. Flight becomes possible when lift overcomes weight and thrust overcomes drag. The two kinds of airfoils used on Army aircraft are symmetrical and asymmetrical.
